

Empowering Insurance Companies with In-Memory Computing

A GridGain Systems In-Memory Computing White Paper

In a time when innovative technologies are upending many industries, the insurance industry faces great opportunities—and significant challenges. Growth continues to be strong: in 2014, the insurance industry was responsible for about 2.6% of U.S. GDP, and net premiums in the U.S. are continuing to rise beyond the 2015 total of \$1.2 trillion. Online and mobile apps are enabling insurance companies to reach a wider range of potential customers, and capabilities such as smart contracts, Robotic Process Automation (RPA), machine learning, and telematics (tracking risk parameters by means of data-transmitting IoT devices) are revolutionizing internal processes and risk assessment.

At the same time, providers are facing increased competition as well as increased customer expectations for immediate response on all of their digital channels. The current climate of economic, political, regulatory, and climate-related uncertainty steps up the pressure to operate efficiently and strategically.

As insurance providers seek to stand out in an increasingly crowded field, technology is a crucial part of maintaining a competitive edge. With consumers expecting instant turn-around on quotes, underwriting, and claims processing, successful providers must process transactions in real-time. They must also be able to scale their capacity quickly to meet usage growth. Plus, they need robust streaming capabilities and sophisticated analytics to help them quickly monitor and analyze the many data streams now relevant to their business.

To achieve this level of performance, scalability, and analytical sophistication, many payments providers are turning to in-memory computing solutions. This white paper will discuss the challenges facing today's insurance industry, the opportunities new technologies can offer, and the crucial edge that providers can gain with solutions such as the GridGain in-memory computing platform.

CHALLENGES FACING INSURANCE PROVIDERS

With the insurance industry changing in significant ways, providers face a host of new challenges, including:

- Increased customer expectations for instant, digital interactions
- Heightened competition from both traditional and nontraditional providers
- Cultural changes affecting insurance models, such as the sharing economy

- Vulnerability to hacking, fraud, and other forms of cyber-crime in the digital marketplace
- A climate of uncertainty with respect to the regulations, the economy, and weather

Let's look at each of these challenges in more detail.

Increased customer expectations. As new methods of digital interaction become the norm, more and more customers expect fast, easy, mobile communication with their insurance providers. Whether they are looking for quotes, policy underwriting, or claims processing and payments, they want the process to be available 24/7 from their tablets and smartphones, as well as from their desktop and laptop computers—and they want the interactions to occur in real time. Plus, they want to interact with their insurance company through a range of portals, including social media.

Heightened competition. Legacy insurance providers seeking to satisfy these increased customer expectations must now compete with agile, tech-savvy startups such as Lemonade, Trov, Fabric, and Ladder. Lemonade uses machine learning and bots to deliver home and renters insurance through a quick-response app. Trov provides on-demand insurance for assets such as computers and cameras through a smartphone app, while Fabric and Ladder sell life insurance through a fast, app-based process. While some of this competition is limited by geography (Trov, for instance, was available only in the U.K. and Australia at the time this was written), these limits are quickly loosening. In general, the availability of insurance online is providing customers with access to a wider range of providers, not just local ones. Plus, comparison-shopping online is getting easier. For example, in the U.K., customers can compare rates and coverage among providers with the help of an A.I.-based insurance-advisory app called Broly. This ease of comparison puts increased pressure on insurance providers to keep rates competitive, as well as to improve their technology, customer service, and customer retention.

Cultural changes. In addition to coping with increased competition and customer expectations, insurance providers are facing some cultural changes that require new insurance models—particularly with respect to the sharing economy. Homeowners renting out rooms through AirBnB and drivers using their vehicles as Uber or Lyft taxis require special considerations with respect to risk assessment. Many providers are looking at usage-based insurance for such situations. For example, the startup Slice, which sells on-demand, short-term insurance for homeshare hosts, who can turn the coverage on and off through an app as needed.

Cyber risk. With the digital revolution and the migration of many business activities online, businesses are now much more vulnerable to hacking, online fraud, and other forms of cyber-crime. On one hand, this change presents a new opportunity to insurers, with businesses seeking cyber insurance against losses related to this type of online activity. However, insurance providers must at the same time figure out how to protect themselves—and the sensitive data of their customers—against cybercrime.

A climate of uncertainty. As an industry based on predictive modeling, the insurance industry is affected particularly strongly by uncertainty. Currently, some significant areas of uncertainty include: the slowly growing economy, with its low interest rates; unusual global weather patterns, with catastrophic events; and political uncertainty in the U.S., with laws regarding health insurance and financial regulations in flux. Insurance providers are facing additional uncertainty around new or strengthened regulatory requirements relating to investments, consumer protection, fraud prevention, and other issues.

Fortunately, even as these challenges have grown for insurance providers, the insurance technology (or “InsurTech”) to help meet these challenges has also evolved quickly, creating new opportunities and innovative solutions.

GAINING AN EDGE THROUGH NEW TECHNOLOGY

Some key ways in which insurance providers are gaining success through new InsurTech include the following:

- Using software robots, artificial intelligence (A.I.), and machine learning to automate and speed up processes
- Using blockchain-based digital ledgers and smart contracts to reduce process steps and increase efficiency
- Using data from sensors, drones, and other smart devices within the Internet of Things (IoT) to provide data-driven coverage that improves risk management and safety
- Implementing high-performance data solutions to enable all of the above, and more

Let’s take a closer look at these InsurTech-enabled trends.

Automating processes with robots and A.I. To help address customer expectations of instant, digital interactions, many insurance providers are turning to techniques such as Robotic Process Automation (RPA), artificial intelligence, and machine learning. RPA, which uses software to replicate easily defin-

able process steps that humans perform on computers, is well suited to many rule-based steps within claims processing. This technique becomes even more powerful when combined with A.I. and machine learning capabilities that can evaluate large amounts of process data and infer subjective decision making capabilities. The speed at which A.I.-based bots can respond to humans makes possible the type of results advertised by Lemonade, the app-based home and renter insurance provider mentioned earlier, which promises “90 seconds to get insured” and “3 minutes to get paid.”

Increasing efficiency with blockchains. The blockchain technology behind the digital currency Bitcoin is being adapted to many applications that can benefit from the efficiency of a decentralized, distributed, peer-to-peer public ledger—including in the insurance industry. With blockchains, many process steps can happen simultaneously, with details centrally posted and verified, rather than going through a series of “middlemen.” (For an in-depth discussion of how blockchains streamline processing even for non-bitcoin transactions, see [“Enable Bitcoin and Blockchain Technology with In-Memory Computing.”](#)) This technology is being used to create peer-to-peer smart contracts—capable of automating many administrative processes—in the Ethereum blockchain.

One example of how this technology is benefiting the insurance industry is the decentralized crop insurance application developed by Etherisc. This application uses a smart contract to check for weather-related crop damage and promises to automatically pay claims to insured parties.

Improving risk management and safety with IoT data. The growth of the Internet of Things has revolutionized the risk-management aspect of the insurance industry, enabling companies to measure risk-related parameters in cars, people, and homes in real time using sensor-enabled, data-transmitting devices. The term telematics, which combines “telecommunications” and “informatics,” is sometimes used to describe this phenomenon, as is usage-based insurance (UBI), since the parameters being measured can paint a picture of how an insured asset is being used.

Auto insurance is one of the first areas in which this practice has been embraced. In fact, the [National Association of Insurance Commissioners has reported](#) that approximately 70% of all auto insurance carriers are expected to use telematics UBI by 2020. That is, auto insurance companies will use sensor in cars to monitor risk-related data, such as miles driven, times of day driven, locations visited, airbag deployment, and acceleration and braking patterns. Collecting such data

allows insurers to improve their risk assessment and better calculate premiums for individual customers. This process can also improve safety and reduce claims, as drivers adapt to lower-risk driving practices to reduce their premiums.

As wearable IoT devices and “smart homes” become more common, telematics is also starting to make an impact in life and health (L & H) insurance, as well as property and casualty (P & C). John Hancock Life Insurance has a program that involves giving Fitbit bands to policy holders—and encouraging wellness—in exchange for discounted life-insurance coverage. In the area of smart home devices, insurers are looking at how to use such devices to detect—and even prevent or mitigate—damage and loss from occurrences such as fire, theft, or floods. For example, a smart thermostat could detect a heater failure during cold weather and notify absent homeowners and insurers to prevent frozen pipes and eventual flooding. Anticipating significant benefits from data-transmitting IoT devices, [60% of insurers in a 2016 survey cited in a magazine](#) reported they had already launched or piloted programs for incorporating connected devices.

Implementing high-performance data solutions. As insurance providers strive to provide real-time, 24/7 services and to quickly process and analyze an avalanche of new data streams, many are finding that their legacy data systems are overwhelmed. To deal with the “performance gap” between their legacy systems and the demands of today’s customers and processes, providers are looking toward high performance state-of-the-art data technology, as described in the next section.

THE CRUCIAL ELEMENT: STATE-OF-THE-ART DATA TECHNOLOGY

To implement the new technologies needed to succeed in today’s insurance market, one ingredient above all is crucial: a technology that can process and analyze enormous amounts of data in real-time.

All of the new technologies being embraced by insurers rely on fast processing of massive amounts of data. Robotic interactions that enable online quotes, policies, and claim-handling must deliver the realtime response that customers expect—even while analyzing large amounts of risk-related and process related data. The data volume can be especially high when machine learning is involved, since this technique requires learning by example, inferring patterns in large amounts of historical data.

Digital ledgers and smart contracts, which can streamline insurance processing, also involve very large amounts of data, since the underlying blockchain technology is peer-to-peer. Subscribers to the blockchain must continually process arriving data blocks, since there is no central repository.

Finally, the IoT data necessary for telematics and usage-based insurance is likely to increase dramatically as smart cars, wearables, and smart home devices become more and more mainstream. Insurers will need to process tremendous amounts of IoT data in real time in order to use the data effectively—especially where risks and safety threats are involved.

When you combine these data needs with other data-processing and analysis needs that are part of the insurance business, such as those related to regulatory compliance, it’s clear that the underlying data processing technology must be state-of-the-art.

In other words, it should have the following characteristics:

- **High-performance and low latency:** Speed is essential for providing the instant insurance transactions that today’s customers expect, as well as for providing real-time risk analysis and processing high volumes of streaming data from IoT devices, as discussed above
- **Scalable:** The ability to easily scale a system up is essential for accommodating fast growth and maintaining high performance even as the volume of customers, policies, and claims increases
- **Flexible and interoperable:** Flexibility (e.g., being open source and cloud-capable) and interoperability are important for offering insurance services from a range of devices, coordinating services such as payments via hubs, and enabling access to diverse data sources
- **Fault-tolerant and highly available:** Data supporting payment of premiums and claims must be maintained with the high level of reliability, availability, and recoverability required for all financial data
- **Secure:** Fully implemented security features are vital for keeping private customer data safe, particularly as IoT devices increase the amount of data collected per customer
- **Capable of sophisticated big data analytics:** The ability to effectively use predictive modeling, complex event processing (CEP), machine learning, and statistical and A.I. techniques is extremely important for supporting real-time risk analysis, fraud prevention, and data-driven business intelligence

Fortunately, there is a data processing technology that is available with these features and is well suited to this type of high speed, big data use case: in-memory computing, as implemented in the GridGain in-memory computing platform.

DEPLOYING IN-MEMORY COMPUTING FOR VELOCITY, VOLUME, AND SCALABILITY IN FINTECH IMPLEMENTATIONS

In-memory computing has become the technology of choice for applications such as insurance that require high-speed data processing and analysis. Because in-memory computing involves keeping data in RAM for extremely fast access, with no slowdowns resulting from moving data between RAM and disk, it is faster than systems built on disk-based databases.

For applications that require heavy analytics and real-time (or near real-time) transaction processing of hundreds or even millions of transactions per second, the market is now moving from disk to in-memory computing. The reasons for this trend involve both performance and Return On Investment (ROI).

1000x Faster. The move from disk to memory is a key factor in improving performance. However, simply moving to memory is not sufficient to guarantee the extremely high memory-processing speeds needed at the enterprise level. Enterprise-level speed requires cluster computing, with multiple machines performing analyses at the same time, and parallel distribution of data. These capabilities are important for providing high availability, disaster recovery, and concurrency across systems—and they are all provided in the GridGain in-memory computing platform. Clients who have implemented the GridGain In-Memory Computing Platform have found that they can process transactions about 1000 times faster.

10x ROI Improvement. The cost of memory has dropped roughly 30% per year since the 1960s, so memory has become much more affordable in recent years. While it may still be slightly more expensive than disk, the performance is so much better that it improves ROI significantly. Clients who have implemented the GridGain in-memory computing platform have seen a tenfold or more improvement in their ROI.

Risk-analysis case study: Finastra Financial Software. One example of a GridGain client excelling in an area relevant to insurance is Finastra, maker of a financial software product focusing on risk management and risk analysis. This software is used by 48 of the world's 50 largest banks. While Finastra is oriented toward banking, its situation is similar to what

insurance providers face: large amounts of data arriving and requiring analysis in real time—analysis that is used, in this case, to create reports for customers.

With GridGain, Finastra was able to build a cluster and serve many customers in a multi-tenant setup that integrates trading systems with cloud-based components. Customers can use this common platform to build their models and analyze their positions across a variety of instruments in real time, thanks to GridGain technology. Felix Grevy, the director of product management for FusionFabric. cloud at Finastra, described the GridGain advantage this way: "With GridGain, we have achieved real-time processing of massive amounts of trade and transaction data, eliminating bottlenecks and enabling us to offer next-generation financial services to our customers.

Financial-services case study: Sberbank. Another noteworthy GridGain Systems customer is Sberbank, the largest bank in Russia and the third largest in Europe. Sberbank was faced with a similar problem to the one currently facing companies who are transitioning from person-to-person, cash-and-credit card-based payments to 24/7 digital, online payment environments. The bank was switching from a more traditional, brick-and-mortar setup—one in which people would come into their offices and manually process a limited number of financial transactions each day, during a limited time period—to a new world with online and mobile customers transacting with them 24/7.

The company forecasted future throughput requirements and determined that it needed to move to a next-generation data-processing platform to handle the expected transaction volume. Sberbank analyzed more than ten potential solutions from vendors in the in-memory computing space and found that the GridGain in-memory computing platform was the most comprehensive solution. The bank concluded that GridGain would provide the next-generation platform with a significant improvement in performance and scalability.

The GridGain in-memory computing platform provided several other important capabilities that Sberbank's next-generation platform would require such as machine-learning and analytics, flexible pricing, artificial intelligence, ease of deployment, hardware independence of cluster components, and a rigorous level of transactional consistency. Of particular importance was the ability to conduct integrity checking and rollback on financial transactions. Sberbank could not find that level of consistency with other in-memory computing solutions.

[In a January 2016 article in RBC](#), Herman Gref, the CEO of Sberbank, said that the bank selected the GridGain Systems technology to build “a platform that will enable the bank to introduce new products within hours, not weeks.” He went on to state that the GridGain in-memory computing platform enables Sberbank to provide “unlimited performance and very high reliability” while being “much cheaper” than the technology used previously. Sberbank is using GridGain’s in-memory computing platform to implement capabilities that could not be provided by the other vendors evaluated—a group that included Oracle®, IBM® and others.

GRIDGAIN SYSTEMS: A LEADER IN IN-MEMORY COMPUTING

The GridGain in-memory computing platform helps Fintech developers consolidate onto a single high-performance and highly scalable big-data solution for transactions and analytics, resulting in lower TCO.

Advanced SQL functionality and API-based support for common programming languages enable rapid deployment. This, coupled with the rapidly decreasing cost of memory, boosts ROI for in-memory computing initiatives, enabling Fintech developers to create solutions that can perform thousands of times better. Any Fintech company seeking speed, security, and rapid deployment can yield the benefits of the GridGain in-memory computing platform.

A Unified High-performance Architecture

The GridGain in-memory computing platform consists of multiple grids connected by a clustered in-memory file system. The In-Memory Data Grid, In-Memory Compute Grid, In-Memory SQL Grid and In-Memory Service Grid are interconnected. Computations occur as close as possible to the data used in the computation. Additional features such as high throughput, low latency, load balancing, caching, in-memory indexing, streaming, Hadoop acceleration and other performance improvements are crucial to success in real-time modeling, processing, and analytics.

Scalability

The GridGain in-memory computing platform excels in terms of scalability, allowing companies to add cluster nodes and memory in real-time with automatic data rebalancing. As a hardware-agnostic solution, clients can choose their preferred hardware for scaling up.

Full SQL Support

GridGain is ANSI SQL-99 compliant and the In-Memory SQL Grid supports DML users can leverage their existing SQL code using the GridGain JDBC and ODBC APIs. For users with existing code bases which are not based on SQL, they can leverage their existing code through supported APIs for Java, .NET, C++, and more.

High Availability

The GridGain in-memory computing platform provides essential high availability features such as data-center replication, automatic failover, fault tolerance, and quick recovery on an enterprise-level scale.

Transaction Processing

The GridGain in-memory computing platform supports ACID-compliant transactions in a number of user-configurable modes.

Security Features

The GridGain in-memory computing platform supports authentication, authorization, multiple encryption levels, tracing, and auditing.

Open Source Framework

GridGain is based on Apache® Ignite™, a popular open source project with many contributors that has been tested globally. GridGain Systems was the original creator of the code contributed to the Apache Software Foundation that became Apache Ignite and fully supports the technology behind Apache Ignite. The [GridGain Enterprise Edition](#) extends the features in Apache Ignite to provide enterprise-level capabilities and services, such as additional security, data center replication, auditing mechanisms, a GUI for management and monitoring, network segmentation, and a recoverable local store.

Production Support

[GridGain Systems Support](#) is available for [GridGain Community Edition](#), [GridGain Enterprise Edition](#) and [GridGain Ultimate Edition](#) users. The Enterprise and Ultimate editions include rolling updates, faster availability of all releases and patches, and 24/7 enterprise-level support.

IN-MEMORY COMPUTING: THE BEST POLICY FOR SUCCESS

The rapid changes in the insurance industry in recent years have brought a host of new challenges to providers, along with new opportunities. To successfully navigate the competitive new terrain, providers need to provide real-time quotes, underwriting, and claims-processing from a wide variety of digital and mobile portals, with the help of techniques such as robotic process automation (RPA) and machine learning. They also need to make strategic use of blockchain-based options such as distributed public ledgers and smart contracts that can help them process and pay claims efficiently. Plus, as IoT devices become an accepted part of risk management through telematics, providers will need to monitor and analyze increasingly massive amounts of streaming data. These changes demand a new level of transactional speed and analytic power.

Fortunately, in-memory computing solutions can now provide the level of performance these companies need. Combining an open source framework with enterprise-level features, the GridGain in-memory computing platform offers a scalable, comprehensive, secure, and affordable solution—an elegant and efficient way to give insurance providers the high-performance edge they need.

Contact GridGain Systems

To learn more about how GridGain can help your business, please email our sales team at sales@gridgain.com, call us at +1 (650) 241-2281 (US) or +44 (0)208 610 0666 (Europe), or complete our [contact form at www.gridgain.com/contact](http://www.gridgain.com/contact) and we will contact you.

About GridGain Systems

GridGain Systems is revolutionizing real-time data access and processing with the GridGain in-memory computing platform built on Apache® Ignite™. GridGain and Apache Ignite are used by tens of thousands of global enterprises in financial services, fintech, software, e-commerce, retail, online business services, healthcare, telecom and other major sectors, with a client list that includes ING, Raymond James, American Express, Societe Generale, Finastra, IHS Markit, ServiceNow, Marketo, RingCentral, American Airlines, Agilent, and UnitedHealthcare. GridGain delivers unprecedented speed and massive scalability to both legacy and greenfield applications. Deployed on a distributed cluster of commodity servers, GridGain software can reside between the application and data layers (RDBMS, NoSQL and Apache® Hadoop®), requiring no rip-and-replace of the existing databases, or it can be deployed as an in-memory transactional SQL database. GridGain is the most comprehensive in-memory computing platform for high-volume ACID transactions, real-time analytics, web-scale applications, continuous learning and hybrid transactional/analytical processing (HTAP). For more information on GridGain products and services, visit www.gridgain.com.
